Background
A mosaic tet(S/M) gene encoding tetracycline resistance has been found in Streptococcus spp., but rarely reported in pneumococci. We assessed a global collection of pneumococcal genomes to identify tet(S/M) and characterise their geographical distribution and genetic background.

Methods
• **Bacterial collection**: We detected the mosaic tet(S/M) encoding tetracycline resistance in a global collection of 12,254 pneumococcal isolates, which represented 30 countries in Africa (59.3%), Asia (17.2%), North America (12.0%), South America (8.3%), and Europe (3.2%). The collection consisted of disease (n=7,391) and carriage (n=4,863) isolates.

• **Processing of data**: Recombination-removed phylogeny was built using GUBBINS and RaxML, antibiotic resistance determinants were detected using ARIBA. Phandango and EasyFig were used to visualise trees and ICE comparison, respectively.

Results
1. The majority of tet(S/M)-positive isolates were collected from invasive disease among children aged ≤ 5 years old in South Africa
The tet(S/M) gene was identified in 130 isolates from South Africa (n=123), Malawi (n=4), and one each from Brazil, Mozambique, and the USA. The majority were isolated from sterile body sites: blood (n=73), cerebral fluid (n=29), and pleural fluid (n=4); and from nasopharynx (n=24). In South Africa, 78.9% (97/123) of tet(S/M)-positive isolates was collected from invasive disease among children aged ≤ 5 years old (Figure 1).

2. The mosaic structure of tet(S/M) in S. pneumoniae was unique from other Streptococcus spp. (Figure 2).

3. The tet(S/M)-positive isolates formed a multidrug-resistant sub-lineage which belong to CC230 (PMEN global clone Denmark4,32, PMEN32)
   • All tet(S/M)-positive isolates belonged to CC230, except for one from Brazil that belonged to CC320.
   • The CC230 tet(S/M)-positive isolates formed a sub-lineage within a CC230 phylogeny (Figure 3).
   • The CC230 tet(S/M) isolates exhibited resistance to penicillin, erythromycin, tetracycline and cotrimoxazole and were mainly associated with serotype 14 (n=127/129), to a lesser extent, serotype 23A (n=2/129)

4. The tet(S/M) gene within CC230 was located in a conserved Tn916 transposon that inserted within ICESp14ST230, a Tn5253-like ICE element that co-carried ermB (Figure 4).

Conclusions
There was a low prevalence of tet(S/M) within the GPS dataset, and the conserved genomic location of tet(S/M) and closely related genetic background suggested a clonal spread of a tet(S/M)-positive CC230 sub-lineage within South Africa.
